

# More Exercises: Data Types and Variables

Please, submit your source code solutions for the described problems to the [Judge System](#).

**Note: These exercises are excluded from your homework!**

## 1. Exchange Integers

Read two integer numbers and, after that, **exchange their values**. Print the variable values before and after the exchange, as shown below:

### Examples

| Input    | Output  |
|----------|---|
| 5<br>10  | Before:<br>a = 5<br>b = 10<br>After:<br>a = 10<br>b = 5   |
| 10<br>20 | Before:<br>a = 10<br>b = 20<br>After:<br>a = 20<br>b = 10 |

### Hints

You may use a **temporary variable** to remember the old value of **a**, then assign the value of **b** to **a**, and then assign the value of the temporary variable to **b**.

## 2. Prime Number Checker

Write a program to check if a number is **prime**. A prime number is a natural number greater than 1, not a product of two smaller natural numbers. For example, the only ways of writing 5 as a product,  $1 \times 5$  or  $5 \times 1$ , involve 5 itself.

The **input** comes as an integer number.

The **output** should be **True** if the number is prime and **False** otherwise.

### Examples

| Input | Output |
|-------|--------|
| 7     | True   |
| 8     | False  |
| 81    | False  |

### 3. Decrypting Messages

On the **first line**, you will receive a **key (integer)**. On the **second line**, you will receive **n** – the number of **lines**, which will **follow**. On the next **n lines** – you will receive a **lower** and an **uppercase** letter per line.

You should **add the key** to **each of the characters** and append them to a **message**. In the end, **print the decrypted message**.

#### Examples

| Input                                     | Output  | Input                                     | Output  |
|---|---------|---|---------|
| 3<br>7<br>P<br>l<br>c<br>q<br>R<br>k<br>f | SoftUni | 1<br>7<br>C<br>d<br>b<br>q<br>x<br>o<br>s | Decrypt |

### 4. Balanced Brackets

On the **first line**, you will receive **n** – the number of lines, which will follow. On the following **n lines**, you will receive **one** of the following:

- Opening bracket – "(",
- Closing bracket – ")" or
- **Random string**

Your task is to find out if the **brackets** are **balanced**. That means after every **opening** bracket should follow a **closing** one. Nested parentheses are **not valid**, and if, for example, **two consecutive opening brackets** exist, the expression should be marked as **unbalanced**. You should print **"BALANCED"** if the parentheses are balanced and **"UNBALANCED"** otherwise.

#### Examples

| Input  | Output   | Input  | Output     |
|--|----------|--|------------|
| 8<br>(<br>5 + 10<br>)<br>* 2 +<br>(<br>5<br>)<br>-12 | BALANCED | 6<br>12 *<br>)<br>10 + 2 -<br>(<br>5 + 10<br>) | UNBALANCED |
